

Oscillating Hydrofoil

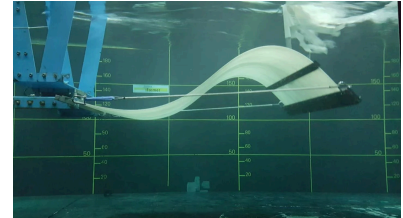

The [oscillating hydrofoil](#) consists of a hydrofoil placed in the direction of current flow that lifts and drags with the current, resulting in a fluid up-and-down motion. These hydrofoils can exist in racks of multiple hydrofoils, on individual arms, or can be elastic and free. They can further be mounted to the sea floor or floating platforms. Very few of these devices exist and the technology is still in development.
