

Overtopping Devices

[Overtopping devices](#) are large funnel-like structures that raise the water level within the structure higher than the surrounding water. The difference in pressure between the surface water and that within the structure's reservoir allows it to move a turbine. Few of these devices exist, and those that do are generally floating, with slack moorings, such as the [Wave Dragon](#). However, the [Panthalassa Ocean-2](#) device, of which is currently being developed for open water deployment, is entirely self propelling and generates AI computational tasks via satellite, requiring no mooring or transmission lines.
